Module 7 – Parallel Computation Patterns (Histogram)

Lecture 7.1 - Histogramming

Objective

- To learn the parallel histogram computation pattern
  - An important, useful computation
  - Very different from all the patterns we have covered so far in terms of output behavior of each thread
  - A good starting point for understanding output interference in parallel computation

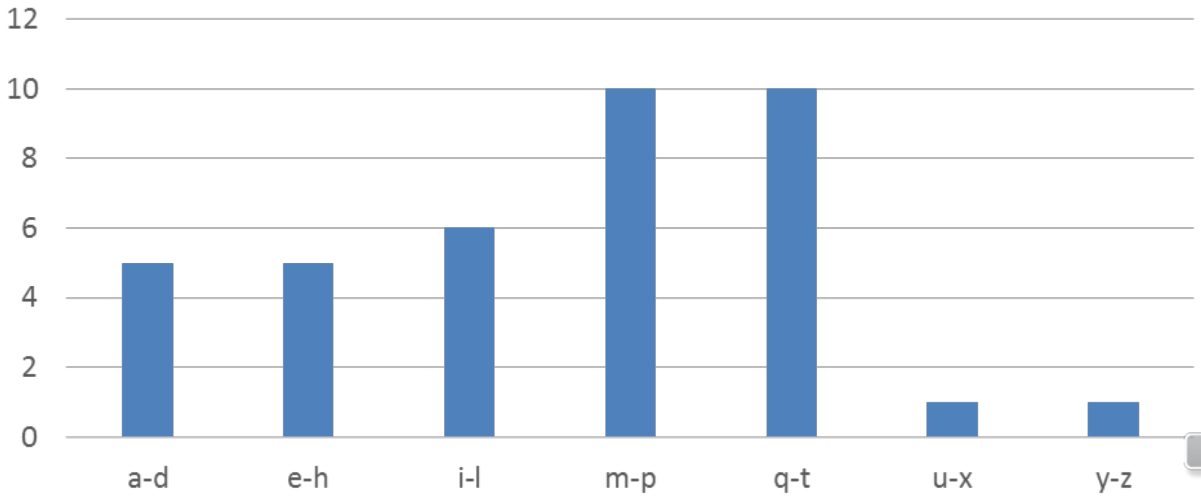
Histogram

- A method for extracting notable features and patterns from large data sets
  - Feature extraction for object recognition in images
  - Fraud detection in credit card transactions
  - Correlating heavenly object movements in astrophysics
  - …

- Basic histograms - for each element in the data set, use the value to identify a “bin counter” to increment

A Text Histogram Example

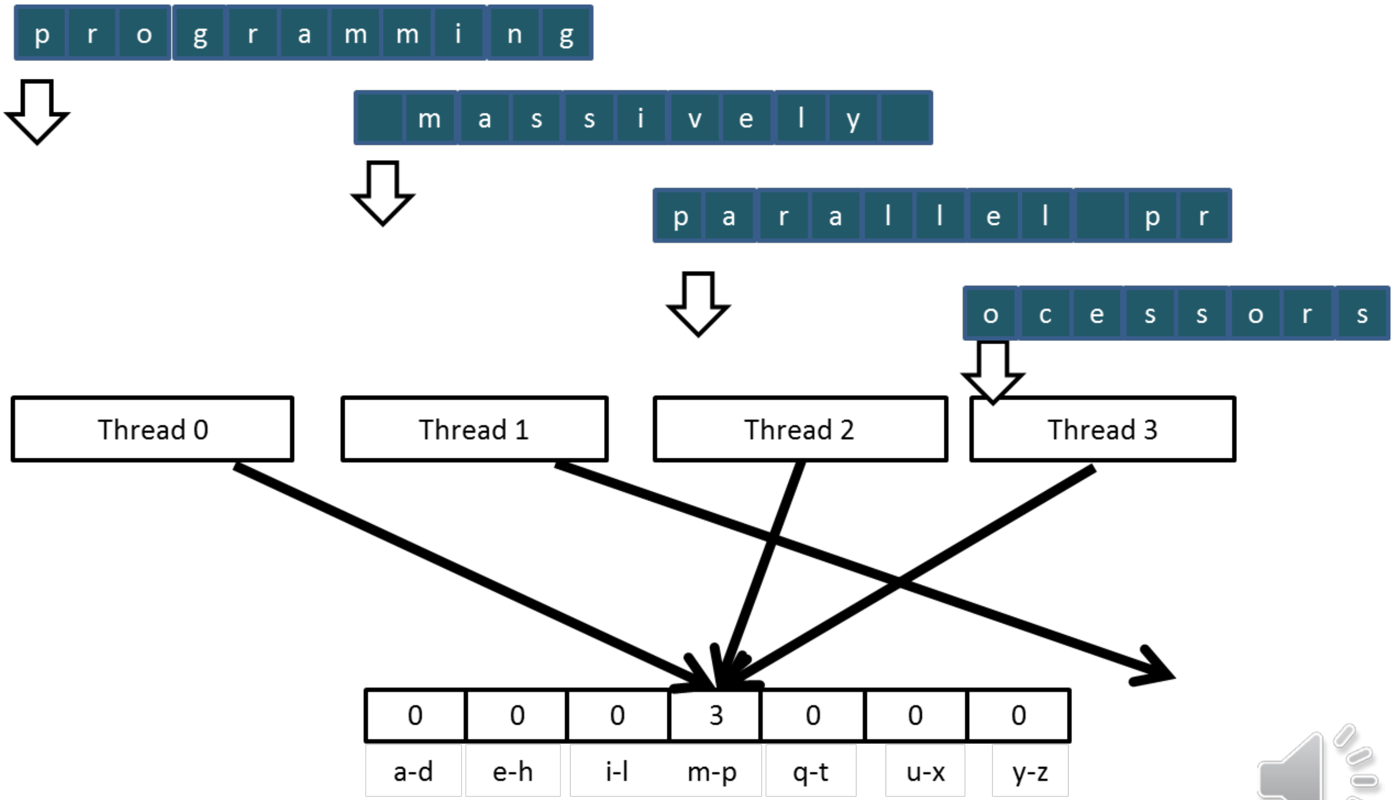
– Define the bins as four-letter sections of the alphabet: a-d, e-h, i-l, n-p, …
– For each character in an input string, increment the appropriate bin counter.
– In the phrase “Programming Massively Parallel Processors” the output histogram is shown below:



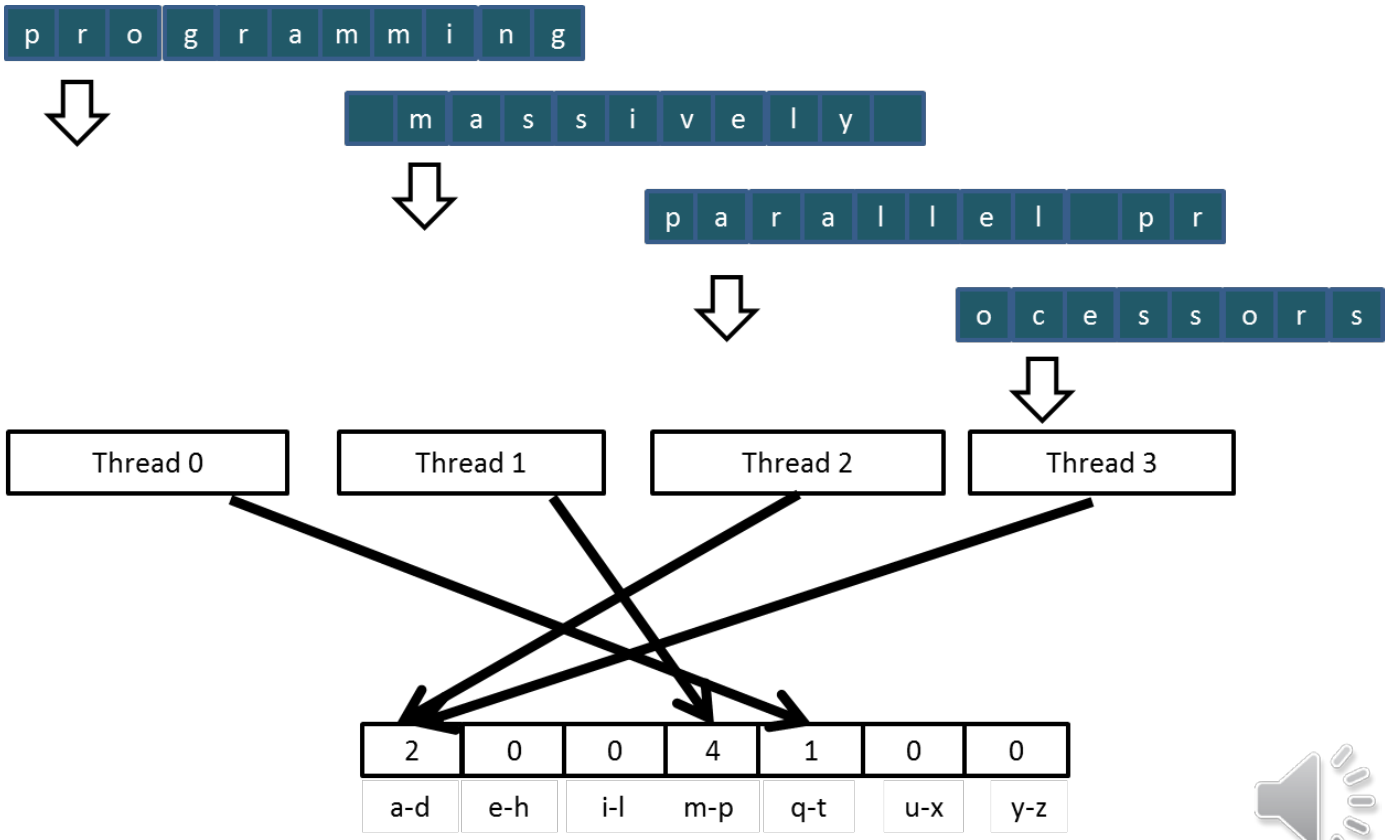
A simple parallel histogram algorithm

- Partition the input into sections
- Have each thread to take a section of the input
- Each thread iterates through its section.
- For each letter, increment the appropriate bin counter

Sectioned Partitioning (Iteration #1)



Sectioned Partitioning (Iteration #2)

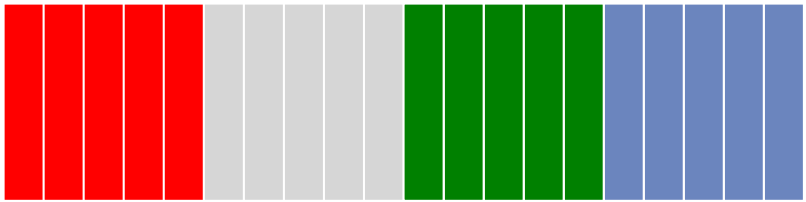


Input Partitioning Affects Memory Access Efficiency

- Sectioned partitioning results in poor memory access efficiency
  - Adjacent threads do not access adjacent memory locations
  - Accesses are not coalesced
  - DRAM bandwidth is poorly utilized

Input Partitioning Affects Memory Access Efficiency

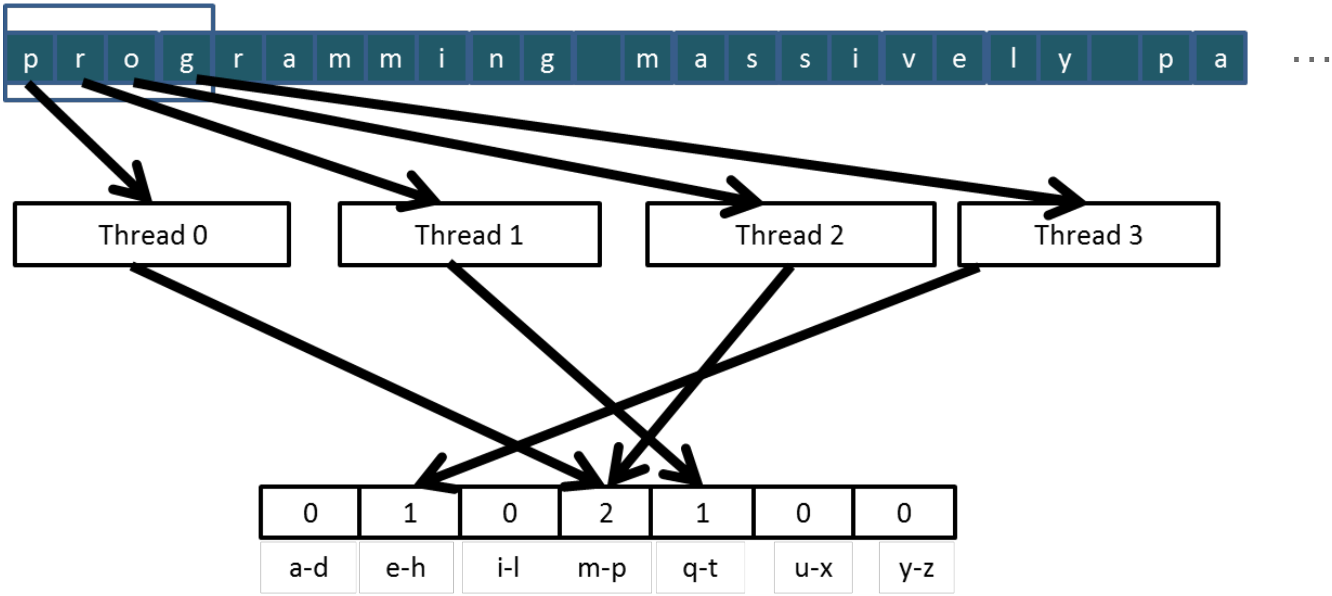
- Sectioned partitioning results in poor memory access efficiency
  - Adjacent threads do not access adjacent memory locations
  - Accesses are not coalesced
  - DRAM bandwidth is poorly utilized



- Change to interleaved partitioning
  - All threads process a contiguous section of elements
  - They all move to the next section and repeat
  - The memory accesses are coalesced

Interleaved Partitioning of Input

– For coalescing and better memory access performance



Interleaved Partitioning (Iteration 2)

Module 7 – Parallel Computation Patterns (Histogram)

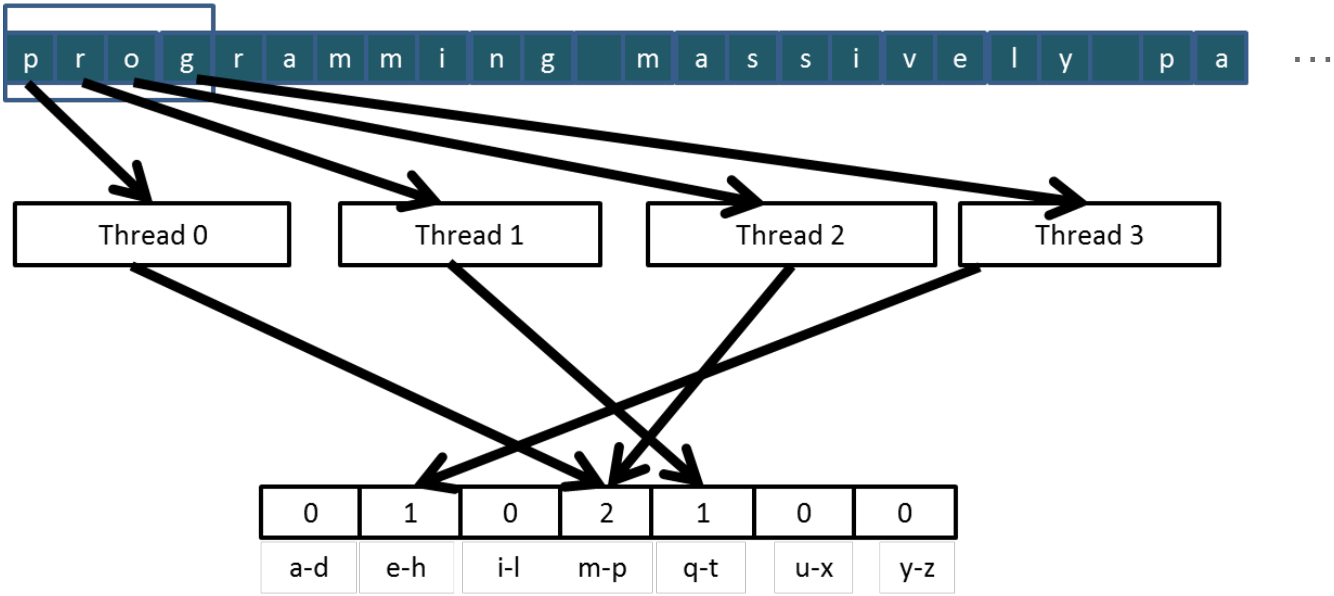
Lecture 7.2 - Introduction to Data Races

Objective

- To understand data races in parallel computing
  - Data races can occur when performing read-modify-write operations
  - Data races can cause errors that are hard to reproduce
  - Atomic operations are designed to eliminate such data races

Read-modify-write in the Text Histogram Example

– For coalescing and better memory access performance



Read-Modify-Write Used in Collaboration Patterns

- For example, multiple bank tellers count the total amount of cash in the safe
- Each grab a pile and count
- Have a central display of the running total
- Whenever someone finishes counting a pile, read the current running total (read) and add the subtotal of the pile to the running total (modify-write)
- A bad outcome
  - Some of the piles were not accounted for in the final total

A Common Parallel Service Pattern

- For example, multiple customer service agents serving waiting customers
- The system maintains two numbers,
  - the number to be given to the next incoming customer (I)
  - the number for the customer to be served next (S)
- The system gives each incoming customer a number (read I) and increments the number to be given to the next customer by 1 (modify-write I)
- A central display shows the number for the customer to be served next
- When an agent becomes available, he/she calls the number (read S) and increments the display number by 1 (modify-write S)
- Bad outcomes
  - Multiple customers receive the same number, only one of them receives service
  - Multiple agents serve the same number

A Common Arbitration Pattern

- For example, multiple customers booking airline tickets in parallel
- Each
  - Brings up a flight seat map (read)
  - Decides on a seat
  - Updates the seat map and marks the selected seat as taken (modify-write)

- A bad outcome
  - Multiple passengers ended up booking the same seat

Data Race in Parallel Thread Execution

thread1:
Old ← Mem[x]
New ← Old + 1
Mem[x] ← New

thread2:
Old ← Mem[x]
New ← Old + 1
Mem[x] ← New

Old and New are per-thread register variables.

Question 1: If Mem[x] was initially 0, what would the value of Mem[x] be after threads 1 and 2 have completed?

Question 2: What does each thread get in their Old variable?

Unfortunately, the answers may vary according to the relative execution timing between the two threads, which is referred to as a **data race**.

Timing Scenario #1

Time	Thread 1	Thread 2
1	(0) Old ← Mem[x]	
2	(1) New ← Old + 1	
3	(1) Mem[x] ← New	
4		(1) Old ← Mem[x]
5		(2) New ← Old + 1
6		(2) Mem[x] ← New

– Thread 1 Old = 0
– Thread 2 Old = 1
– Mem[x] = 2 after the sequence

Timing Scenario #2

Time	Thread 1	Thread 2
1		(0) Old ← Mem[x]
2		(1) New ← Old + 1
3		(1) Mem[x] ← New
4	(1) Old ← Mem[x]	
5	(2) New ← Old + 1	
6	(2) Mem[x] ← New	

– Thread 1 Old = 1
– Thread 2 Old = 0
– Mem[x] = 2 after the sequence

Timing Scenario #3

Time	Thread 1	Thread 2
1	(0) Old ← Mem[x]	
2	(1) New ← Old + 1	
3		(0) Old ← Mem[x]
4	(1) Mem[x] ← New	
5		(1) New ← Old + 1
6		(1) Mem[x] ← New

- Thread 1 Old = 0
- Thread 2 Old = 0
- Mem[x] = 1 after the sequence

Timing Scenario #4

Time	Thread 1	Thread 2
1		(0) Old ← Mem[x]
2		(1) New ← Old + 1
3	(0) Old ← Mem[x]	
4		(1) Mem[x] ← New
5	(1) New ← Old + 1	
6	(1) Mem[x] ← New	

- Thread 1 Old = 0
- Thread 2 Old = 0
- Mem[x] = 1 after the sequence

Purpose of Atomic Operations – To Ensure Good Outcomes

thread1: Old ← Mem[x]
New ← Old + 1
Mem[x] ← New

thread2: Old ← Mem[x]
New ← Old + 1
Mem[x] ← New

Or

thread2: Old ← Mem[x]
New ← Old + 1
Mem[x] ← New

thread1: Old ← Mem[x]
New ← Old + 1
Mem[x] ← New

Module 7 – Parallel Computation Patterns (Histogram)

Lecture 7.3 - Atomic Operations in CUDA

Objective

- To learn to use atomic operations in parallel programming
  - Atomic operation concepts
  - Types of atomic operations in CUDA
  - Intrinsic functions
  - A basic histogram kernel

Data Race Without Atomic Operations

Mem[x] initialized to 0

thread1: Old ← Mem[x]

time

New ← Old + 1

Mem[x] ← New

thread2: Old ← Mem[x]

New ← Old + 1

Mem[x] ← New

- Both threads receive 0 in Old
- Mem[x] becomes 1

Key Concepts of Atomic Operations

- A read-modify-write operation performed by a single hardware instruction on a memory location *address*
  - Read the old value, calculate a new value, and write the new value to the location
- The hardware ensures that no other threads can perform another read-modify-write operation on the same location until the current atomic operation is complete
  - Any other threads that attempt to perform an atomic operation on the same location will typically be held in a queue
  - All threads perform their atomic operations **serially** on the same location

Atomic Operations in CUDA

- Performed by calling functions that are translated into single instructions (a.k.a. *intrinsic functions* or *intrinsics*)
  - Atomic add, sub, inc, dec, min, max, exch (exchange), CAS (compare and swap)
  - Read CUDA C programming Guide 4.0 or later for details

- Atomic Add

```
int atomicAdd(int* address, int val);
```

  - reads the 32-bit word **old** from the location pointed to by **address** in global or shared memory, computes (**old + val**), and stores the result back to memory at the same address. The function returns **old**.

More Atomic Adds in CUDA

- Unsigned 32-bit integer atomic add

```
unsigned int atomicAdd(unsigned int* address,
    unsigned int val);
```

- Unsigned 64-bit integer atomic add

```
unsigned long long int atomicAdd(unsigned long long
    int* address, unsigned long long int val);
```

- Single-precision floating-point atomic add (capability > 2.0)
  - `float atomicAdd(float* address, float val);`

A Basic Text Histogram Kernel

- The kernel receives a pointer to the input buffer of byte values
- Each thread process the input in a strided pattern

```
__global__ void histo_kernel(unsigned char *buffer,
        long size, unsigned int *histo)
{
    int i = threadIdx.x + blockIdx.x * blockDim.x;

// stride is total number of threads
    int stride = blockDim.x * gridDim.x;

 // All threads handle blockDim.x * gridDim.x
   // consecutive elements
   while (i < size) {
       atomicAdd( &(histo[buffer[i]]), 1);
       i += stride;
   }
}
```

A Basic Histogram Kernel (cont.)

- The kernel receives a pointer to the input buffer of byte values
- Each thread process the input in a strided pattern

```
__global__ void histo_kernel(unsigned char *buffer,
       long size, unsigned int *histo)
{
    int i = threadIdx.x + blockIdx.x * blockDim.x;

// stride is total number of threads
    int stride = blockDim.x * gridDim.x;

 // All threads handle blockDim.x * gridDim.x
   // consecutive elements
   while (i < size) {
      int alphabet_position = buffer[i] – “a”;
      if (alphabet_position >= 0 && alpha_position < 26)
       atomicAdd(&(histo[alphabet_position/4]), 1);
       i += stride;
   }
}
```
